## AUTHORS

Randall Z. Davis is a Fishery Biologist for the Alaska Department of Fish and Game, Commercial Fisheries Management and Development Division, Region II, Upper Cook Inlet, 34828 Kalifornsky Beach Road Suite B, Soldotna, AK 99669.

Bruce E. King is an Assistant Research Project Leader for the Alaska Department of Fish and Game, Commercial Fisheries Management and Development Division, Region II, Upper Cook Inlet, 34828 Kalifornsky Beach Road Suite B, Soldotna, AK 99669.

## ACKNOWLEDGMENTS

We would like to acknowledge the work of the permanent seasonal staff responsible for collecting the data: Kenai River sonar - David Westerman (Crew Leader), Jennifer Brannen, Dennis Beliveau, Mike Byerly ; Kasilof River Sonar - Lowell Fair (Crew Leader), Pako Lehtinen, Phil Morin; Yentna River Sonar - Morris Lambdin (Crew Leader), Stanley Walker, Wayne Lehtinen; Crescent River Sonar - Mark Schlenker (Crew Leader) and Cindi Preller-Schlenker.

Stan Carlson, Alaska Department of Fish and Game biometrician, Soldotna, contributed to the data analysis.

We also acknowledge the Alaska Department of Fish and Game (ADF&G) Sport Fish Division, Soldotna, for data collected at Russian River weir (Kenai River drainage) and ADF&G Sport Fish Division, Palmer, for Susitna River coho and chinook salmon stream survey counts. Cook Inlet Aquaculture Association provided weir counts from Hidden Creek (Kenai River tributary), Bear Creek (Tustumena Lake, Kasilof River drainage) and Chelatna Lake (Yentna River drainage).

## ABSTRACT

Sockeye salmon *Oncorhynchus nerka* spawning escapements into four river systems of Upper Cook Inlet, Alaska, were estimated using side-scanning sonar equipment. Estimated sockeye salmon escapements were 630,447 into the Kenai River, 204,935 into the Kasilof River, 52,311 into the Crescent River, and 121,220 into the Yentna River. Indices of escapements of other salmon species into the Yentna River were also obtained by sonar: 103,990 pink *O. gorbuscha*, 31,473 chum *O. keta*, and 74,406 coho *O. kitsutch* salmon. Sockeye salmon in the Kenai River were primarily distributed within three age classes: 1.2 (31.9%), 2.3 (31.3%) and 1.3 (26.4%). Kasilof River sockeye salmon were primarily age: 1.2 (44.0%); 2.2 (25.0%); 1.3 (15.5%) and 2.3 (15.3%). Age-2.3 sockeye salmon were the most abundant (61.7%) age class in the Crescent River, followed by age class 1.3 (18.4%). Yentna River sockeye salmon were primarily age: 1.3 (51.3%), 1.2 (19.7%), and 2.3 (11.6%). Length and sex ratio data were collected for sockeye salmon in each river. Sockeye salmon migration routes in all rivers was near shore. Peak salmon counts were recorded during the evening hours in the Kenai and Kasilof Rivers, and during the evening and early morning hours in the Yentna River. Peak hourly counts in the Crescent River were related to the post meridiem high tides.

KEY WORDS: Alaska, Cook Inlet, salmon, Kenai River, Kasilof River, Crescent River, Yentna River, Susitna River, age/sex/size, sonar, escapement enumeration.

## INTRODUCTION

Prior to 1968, sockeye salmon escapement estimates in Upper Cook Inlet (UCI), Alaska (Figure 1) were based on surveys of clear water spawning areas and provided no information about the distribution or number of sockeye salmon which spawned in glacially occluded waters (King and Davis 1989). Commercial and recreational fishery management efforts were further hampered by lack of daily and cumulative estimates of escapement. These constraints were significantly reduced by the development of hydroacoustic techniques to enumerate sockeye salmon in some glacial tributaries of UCI. Hydroacoustic enumeration of escapement began on the Kenai and Kasilof Rivers in 1968, was expanded to the Susitna River in 1978 and to the Crescent River in 1980. The Susitna River counting site was abandoned in 1985, and in 1986 counting operations began on the Yentna River, a major tributary of the Susitna River. Results of escapement enumeration studies were documented by Waltemyer et al. (1980), Tarbox et al. (1981, 1983), King and Tarbox (1984, 1986, 1987, 1988, 1989a, 1990 and 1991), King (1990), King et al. (1989b, 1992), King and Davis (1989, 1992), Davis and King (1993, 1994 and 1995), Davis et al. (1993), and Namtvedt et al. (1979).

The program objectives of UCI escapement projects in 1995 were to estimate (1) the daily and cumulative number of sockeye salmon entering the Kenai, Kasilof, Crescent, and Yentna Rivers, and (2) the age, length, and sex composition of those escapements. Indices of abundance were also obtained for Yentna River pink, chum and coho salmon.

## METHODS

*Bendix Corporation*<sup>1</sup> side-scanning sonar counters described by King and Tarbox (1989a), Gaudet (1983) and Bendix Corp. (1980 and 1984) were used to enumerate salmon escapements. Pulse width was 100 ms and the frequency was 515 KHz. Two- and four-degree transducer elements were multiplexed in an alternating mode. The counting threshold was preset at approximately -38 db by the manufacturer. Detection level could be lowered by increasing gain to the system. Counters were operated without artificial substrates in the Kenai, Crescent and Yentna Rivers. A technical consultant tested the counters for proper operation prior to deployment, and reinspected counters when migrating fish densities neared maximum levels in each river system (A. Menin, Hydroacoustic Consulting, Sylmar, CA).

Project operational dates were: 1 July through 14 August on the Kenai River; 12 June through 4 August on the Kasilof River; 28 June through 8 August on the Crescent River; and 7 July through 10 August on the Yentna River. Counting operations ceased when daily counts were < 1% of the

---

<sup>1</sup>Use of a company's name does not constitute product endorsement.

cumulative count for 3 consecutive days. Kenai and Kasilof River counting operation cessation criteria were not instituted until cessation of continuous commercial fishing.

Raw hourly output data were edited to account for debris, bottom echoes, or other sources of non-fish counts. Hourly sonar counts by day were entered into a data-base program which calculated a daily average hourly count for inshore (1-6) and offshore (7-12) sonar sectors by

$$Ca = Cb/N, \quad (1)$$

where:

Ca = average count per sector per hour;

Cb = valid hourly counts for all inshore or offshore sectors; and

N = number of sector per hour units which contained only valid counts.

The average count was then substituted into any sector/hour block where counts were deleted through editing. Sonar counts collected from the north bank of the Crescent River received the same treatment but calculations were made manually and computer entry of data occurred post-season. The daily average hourly count for the south bank of the Crescent River was calculated for each sector by:

$$Cc = Cd/N, \quad (2)$$

where:

Cc = average count per sector per hour for the Crescent River south bank;

Cd = valid Crescent River south bank hourly counts per sector; and

N = number of hour units per sector which contained only valid counts.

All counts recorded on the south bank at Crescent River occurred in sectors one (93.5%) and two (6.5%) of the counting range. Printer skips (treated as false counts) regularly occurred in sectors one through six. Hourly averages for each sector were substituted where skips occurred or counts were deleted. Because of the spacial distribution of fish migrating adjacent to this bank, the method used for the treatment of false counts provided a more accurate estimate of daily escapement because it did not place a high hourly average count derived from sector one or two into sectors where very few targets were detected.

Temporal and spacial behavior of sockeye salmon was assessed by examining distribution of fish by sector, hourly passage rate, bank preference, and cumulative proportion of sonar counts by day. Counting range is the length of the ensonified area in which counting occurs. Counting range for the counter operated at on the north bank of the Crescent River ranged from 8.8 m to 9.1 m and the counting range for the south bank was 20.1 m. Counting range for the north bank of the Kenai River was 13.1 m to 17.1 m and 8.8 m to 9.1 m for the south bank. An extended weir was erected on the south bank of the Kenai River enabling positioning of the transducer further from the bank. Counting ranges at the Kasilof River were 11.3 m to 12.5 m on the north bank and 12.8 m to 14.3 m on the south bank. In the Yentna River, counting range for the north bank was 8.8 m to 10.0 m. On the south bank fish were counted between 4.9 m to 5.5 m. Reported ranges encompassed the

period when 80% (10%-90%) of the run occurred and the average counting range employed was used for descriptive purposes. Transducer distance from shore varied among systems and is not reflected in the reported counting range.

Transducer orientation was accomplished by remotely controlled rotators except on the Kasilof River and the south bank of the Kenai River. Correct orientation of the acoustic axis was tested periodically by the use of an artificial target. An air-tight plastic sphere was weighted and moved through the ensonified area at various distances from the transducer. Simultaneous detection of the target by the counter and visual recognition on an oscilloscope verified correct axis orientation. Transducers were moved nearer shore as water depth increased. Fish passage between (behind) the transducers and the bank was prevented by the use of weirs.

Counters were generally monitored 0700-2400 h on the Kasilof, Crescent and Yentna Rivers, and throughout the 24 h period on the Kenai River. In addition to regularly scheduled monitoring, intensified monitoring was conducted during episodic fish passage. In all cases, visual counts from an oscilloscope were compared to the counts accumulated by the counter during a minimum 10-min period or for a minimum oscilloscope count of 100 fish. During periods of low density passage (<500 fish per hour), Kenai and Yentna River oscilloscope/counter observations were made at a minimum of 1 h per bank each day. When passage rates reached 500 fish per hour, minimum observation time increased to 2 h per bank per day. Kasilof and Crescent River counters were monitored for a minimum of 2 h per bank per day. If a relative error greater than 20% occurred between targets counted on the oscilloscope and targets recorded by the counter, counter adjustments were made to reduce the relative error. However, operators typically made adjustments to the counters to accommodate for less than 20% relative error. The basic counter adjustment consisted of changing the pulse repetition rate.

Information used to estimate species composition of sonar counts, and age, length, and sex composition of sockeye salmon escapements was obtained from salmon captured in fish wheels. Fish wheels were located on the north banks of the Kenai, Kasilof, and Crescent Rivers (1 at each site), and on both banks of the Yentna River. Fish wheels were operated up to 24 h per day at Yentna River, and during daylight hours at Crescent and Kasilof Rivers. The Kenai River fish wheel was typically operated during evening hours when the passage rate and proximity to shore of migrating sockeye salmon maximized capture rate. The fish wheel was generally stopped when operators estimated the minimum sample size required to provide age, sex and length data was attained. Fish wheel catches at the Yentna River site were expanded for each 24 h period based on the hourly catch rate during the hours of operation by

$$Fd = (Fh/H) 24, \quad (3)$$

where:

Fd = expanded fish wheel catch for 24 hours;

Fh = fish wheel catch for hours operated; and

H = hours fish wheel operated.

In the Kenai and Kasilof Rivers all sonar counts were treated as sockeye salmon. In the Yentna River, daily fish wheel catches were grouped into sample sizes of at least 150 salmon to apportion sonar counts. Actual (not adjusted to 24 h) fish wheel catches were used to apportion sonar counts in the Crescent River, and, because of their size and number, Dolly Varden char were included in sonar count apportionment at Crescent River. Dolly Varden char were marked and released to verify that captured fish passing the sonar counters were migrating fish.

Factors influencing the accuracy of escapement estimates for pink, coho, chum, and chinook salmon in the Yentna River were discussed by Tarbox et al. (1981, 1983). Counts apportioned to these species in 1995 were considered to be index counts.

Sample sizes for estimating sockeye salmon age composition were based on methods for estimating multinomial proportions developed by Thompson (1987). Minimum sample sizes were calculated so that the estimated proportion of each major age class was within 5% of the true proportion 90% of the time. Previous years age composition proportions were analyzed to determine adequate sample sizes for a variety of age class ratios. The largest sample size calculated in this manner was chosen as a minimum sample size for 1995. The minimum sample size was increased by 10% to account for unreadable scales, and this number was used as the total sample size required. Sockeye salmon scale samples were collected daily from the Kenai, Kasilof, Crescent, and Yentna Rivers. The number of salmon sampled for age composition per day was based on a percentage of the previous day's escapement count. These percentages were calculated by dividing the total season sample size by the anticipated total escapement.

To detect shifts in age class proportions over time, sockeye salmon age class samples were divided into four periods of approximately equal sample size and tested using the chi-square test of independence. The initial test included all periods. If a significant difference was detected, each period was then tested against the following period to determine at what point the age class shift occurred.

Mid-eye to fork-of-tail length (mm) and sex were also recorded for all sockeye salmon sampled. Sex ratios and mean lengths were calculated by grouping all samples together regardless of type or timing of sampling. Age classes which were  $\geq 10\%$  of the total escapement in each river were included in the age and length composition tables.

## RESULTS

### *Kenai River*

An estimated 630,447 sockeye salmon migrated past the Kenai River sonar site (Table 1) from 1 July through 14 August. The desired escapement goal range for this drainage is 400,000-700,000 fish. The estimated sockeye salmon spawning escapement (sonar count minus sport harvest above the Soldotna bridge) was 519,991 fish (Table 2). A total of 7,542 sockeye salmon were passed at

the Hidden Lake weir. The late-run Russian River sockeye salmon escapement totaled 74,461 fish (Table 3).

Eighty percent of the sockeye salmon escapement passed the sonar counters in 31 d (Table 4; mean=19 d; range for 1979-95=6-31 d). The midpoint of the escapement was 31 July. Peak counts occurred on 25 July when 62,716 targets were detected (Table 5). Sockeye salmon migration along the north bank of the river accounted for 52.0% of the total escapement (Table 6). There were three distinct peaks in the daily numbers of fish passing the counters (Figure 2).

Distribution of the salmon migration adjacent to the north bank was predominantly (94.4%) within 10.8 m of the transducer. Salmon distribution adjacent to the south bank was more shore oriented, with 98.1% of the counts within 6.1 m of the transducer (Figure 3).

A pattern of increased salmon passage in the evening hours was observed on both banks but was more pronounced on the south bank (Figure 4,5). Fish passage measured 1800-0200 h accounted for 48.6% of the total migration.

A total of 3,022 sockeye salmon were captured in the fish wheel (Table 7), from which 712 scale samples, sexes, and lengths were obtained. The largest component (31.9%) of the sockeye salmon escapement was age-1.2 fish, followed by -2.3 (31.3%) and -1.3 (26.4%) fish (Table 8). Mean length by sex was within historical bounds for all age classes (Table 9). The male-to-female ratios fell within historical bounds. Female spawners constituted 51.3% of the total escapement. Length composition was within historical bounds but 2-ocean fish tended toward the large end of the range.

Chi-square testing of changes in age class proportions over all periods detected a significant ( $df=9$ ,  $\chi^2=23.7$ ,  $p=.005$ ) difference. A significant increase in the proportion of 2-ocean fish and decrease in the proportion of 3-ocean fish ( $df=3$ ,  $\chi^2=20.01$ ,  $p=.001$ ) occurred between period 3 (26-29 July) and period 4 (30 July-11 August).

Age-1.3 and -2.3 sockeye salmon were bound primarily for Quartz Creek, Tern Lake, the mainstem river, and the shorelines and outlets of Kenai and Skilak Lakes. Late-run sockeye salmon bound for Russian River (above the falls) were predominantly age-2.2 (31.9%), -2.3 (31.6%) and -2.1 (26.9%) fish (Marsh 1995), while those bound for Hidden Lake were predominantly age 1.2 (Fandrei 1995).

#### *Kasilof River*

A total of 204,935 sockeye salmon were counted at the Kasilof River sonar site from 15 June through 7 August (Table 10). The desired escapement range for this system is 150,000-250,000 sockeye salmon. Brood stock for artificial propagation at the Crooked Creek Hatchery (12,416 fish) were taken from Bear Creek (Fandrei 1995, Table 11). The index area spawning escapement estimate for Bear Creek was 29,017 sockeye salmon (Table 12).

The midpoint of the sockeye salmon escapement occurred on 14 July, 1 d after the mean for the previous 16 years (range 1-22 July; Table 13). Eighty percent of the escapement occurred in 30 d, 2 d less than the historical mean (1979-94).

Sixty-two percent of the salmon counts occurred on the south bank (Table 6). Spacial distribution adjacent to the north bank was near shore, where 95.6% of the salmon migrated within 10.0 m of the transducer. Fish passage on the south bank was similar (97.1% of the salmon were within 9.9 m of the transducer, Figure 6).

The average hourly passage rate on the north bank exceeded the 4.2% average for a consistent passage rate between 1400-2100 h and at 0700 h and 1000 h. Two periods had passage rates higher than the consistent passage rate on the south bank: 0600-1000 h and 1900-2200 h. Salmon counted during these hours on the north bank accounted for 47.7% of the total and 45.2% of the south bank total. A more consistent passage rate was observed on the north bank than on the south bank (Figure 7). There was one major peak and two minor peaks in daily passage of fish past the counting site (Figure 2).

A total of 2,023 sockeye salmon were captured in the Kaslof River fish wheel (Table 14), of which 587 were sampled for age, length, and sex characteristics. Age-1.2 (44.0%), -2.2 (25.0%), -1.3 (15.5%) and -2.3 (15.3%) sockeye salmon were the predominant age classes (Table 15). Mean lengths by sex were within the historical range (Table 16), as were the male-to-female ratios for all age classes. Female spawners comprised 55.0% of the escapement.

Chi-square testing of all periods combined detected a significant ( $df=9$ ,  $\chi^2=43.14$ ,  $p=.001$ ) change in age class proportions over time. Testing among periods detected a significant increase in the proportion of 2-ocean fish and decrease in the proportion of 3- ocean fish ( $df=3$ ,  $\chi^2 = 28.88$ ,  $p=.001$ ) between periods 1 (21 June-2 July) and 2 (3 July-17 July).

#### *Crescent River*

A total of 64,077 salmon were counted at the Crescent River sonar site from 28 June through 8 August (Table 17). Sockeye salmon escapement was estimated to have been 52,311 fish or 81.7% of the total salmon escapement (Table 18). The desired sockeye salmon escapement goal for this system is 50,000 to 100,000 fish.

The midpoint of the sockeye salmon escapement occurred on 22 July, 5 d after the date of the historical mean, and 80% of the escapement passed the site in 23 d (Table 19). The peak in daily passage occurred on 22 July (Figure 2). Run timing between banks was similar. Sixty eight percent of the fish migrated along the north bank (Table 6).

Spacial distribution of fish was strongly shore oriented, with 100.0% of the south bank counts within 3.4 m of the transducer and 94.9% of the north bank counts within 4.8 m of the transducer (Figure 8). One peak in the migration was observed (Figure 2). Fish migrated adjacent to the north

bank at rates which exceeded the hourly average for a constant passage rate from 1600-2400 h (Figure 5). Sonar counts during those hours were 55.6% of the bank total. On the south bank the highest hourly passage rates occurred between 1300-2100 h (Figure 9), accounting for 66.6% of the bank total.

A total of 1,539 sockeye salmon were captured in the fish wheel (Table 20), of which 435 were sampled for age, length, and sex data. Age-2.3 fish were the most abundant (61.7%), with the other major component of the escapement represented by age-1.3 fish (18.4%; Table 21). Average lengths by sex were within the bounds of previous years observations (Table 22). Male-to-female ratios were within historical bounds. Females accounted for 55.8% of the total sockeye salmon escapement.

Crescent River hourly fish passage rates peaked during the afternoon and evening hours following high tides (Figure 10). The peak hour of fish passage on the north bank occurred after the post meridiem high tide on 41 of the 42 d of operation and on the south bank on 32 of the 42d of the enumeration operation.

Chi-square testing of age class proportions detected a marginal change over time among age classes ( $df=9$ ,  $\chi^2=16.46$ ,  $p=.001$ ).

Age and length composition of the sockeye salmon escapement in the Crescent River was typical of previous years, however, age-2.2 males were the smallest on record.

There were no recaptures of marked Dolly Varden char.

### *Yentna River*

From 7 July through 10 August, 331,393 salmon were counted at the Yentna River sonar site (Table 23), of which an estimated 121,220 were sockeye salmon. The escapement goal range for the Yentna River is 100,000-150,000 sockeye salmon. Sonar counts apportioned to species other than sockeye salmon were: pink salmon, 103,990; coho salmon, 74,406; chum salmon, 31,473; and chinook salmon, 346 (Table 24). Estimates of coho and chinook salmon escapements for other tributaries of the Susitna River were also made (Table 25). No estimates for pink or chum salmon were available for the Susitna River above its confluence with the Yentna River.

The midpoint of the sockeye salmon escapement occurred on 26 July, the same date as the historical mean. Eighty percent of the escapement passed the counters in 15 d (Table 26). Run timing was not appreciably different by bank. Eighty nine percent of the sockeye salmon migrated adjacent to the south bank (Table 6).

Of the salmon counted from the south bank, 91.7% were within 2.8 m of the transducer (Figure 11). On the north bank, 94.2% of the salmon were counted within 4.8 m of the transducer.

Fish passage rates increased during afternoon and evening hours (Figure 12). The seasonal hourly passage rate on the north bank met or exceeded the average for a constant hourly passage rate (4.2%) 1700-0200 h (Figure 5). Counts accumulated during these hours accounted for 55.7% of the north bank total. The percentage per hour for a constant hourly passage rate was exceeded 1500-2300 h on the south bank. Counts accumulated during these hours accounted for 42.6 % of the south bank total. There were two distinct peaks in the daily numbers of fish passing the counters (Figure 2).

A total of 3,552 sockeye salmon were captured in fish wheels at Yentna Station (Tables 27; 28), of which 507 were sampled for age, sex, and length data. The major components of the escapement were ages 1.3 (51.3%), 1.2 (19.7%), and 2.3 (11.6%; Table 29). Mean lengths and mate-to-female ratios for all age classes fell within historical bounds (Table 30). Female spawners composed 50.6% of the total sockeye salmon escapement.

The proportion of age-1.2 fish decreased and the proportion of age-1.3 fish increased ( $df=3$ ,  $\chi^2=8.502$ ,  $p=.037$ ) between period 3 (26-28 July) and period 4 (29 July-8 August). However, all periods were tested together and no significant ( $df=9$ ,  $\chi^2=14.11$ ,  $p=0.118$ ) changes were detected.

Eighty percent of the pink salmon escapement occurred in 11 d, with the midpoint occurring on 26 July (Table 31). Pink salmon run duration (80%) in the Yentna River has ranged 9 to 21 d. Migratory timing has been remarkably consistent, with the midpoint occurring between 25 and 30 July in 13 of the 15 years for which data is available.

## DISCUSSION

The 1995 field season and sonar counting operations were similar to past years. Counting conditions on all rivers were thought to be within design and operational tolerances of the Bendix side-scanning sonar system because (1) salmon passage was inshore and near the bottom during the peak of the run, (2) salmon densities were generally adequate for system adjustment, and (3) one species, sockeye salmon, composed most of the run except in Yentna River (37%).

### *Kenai River*

Species apportionment of sonar counts was discontinued in 1995 because we perceived a potential problem in the apportionment process when disproportionate numbers of non-sockeye salmon species appear in the fish wheel catch. Additionally, we considered the numbers of fish of other species as insignificant during the time sockeye salmon are being counted under normal run timing circumstances (salmon species other than sockeye salmon composed 1.0% of the fish wheel catch in 1995). If run timing differences dictated, species apportionment of sonar counts would again be instituted. Counts of other species are of no value as index counts as extended run duration and offshore distribution combine to limit the usefulness of these data.

### *Kasilof River*

Run timing, counter limitations, and spawning locations relative to the sonar site made sonar escapement estimates for Kasilof River pink, coho, and chinook salmon impractical. Coho salmon entered the river primarily in August (G. Kyle, ADF&G, Soldotna, personal communication). The proportion of pink salmon was not known, but the average historical proportion of the pink salmon in the Kasilof River escapement is 1.9% (range 0.2-6.4%). Early- and late-run chinook salmon migrated past the sonar site during the time when sockeye were counted, but no counts were apportioned to this species. We believe that the ratio of sockeye salmon to chinook salmon captured in the fish wheel has been biased toward chinook salmon during the latter portion of the run, resulting in total chinook estimates that exceed the actual spawners passing the counting site. The error associated with apportionment of chinook salmon counts to sockeye salmon is more acceptable than an inflated chinook salmon estimate.

### *Crescent River*

Prior to 1993, fish were collected for species composition with drifted gill nets and a fish trap. The installation of a fish wheel at Crescent River provided a larger sample size and probably reduced the degree of size selectivity inherent to the gear types formerly used. Dolly Varden char, which had not appeared in the catch in previous years, appeared in the fish wheel catch in 1993. We determined that the char captured at Crescent River were of adequate size to meet target detection thresholds of the counters and included them in the apportionment of daily sonar counts in 1993-95. We also concluded that these fish were migratory based on morphological characteristics and results of marking all Dolly Varden char captured in 1993-94. Of the Dolly Varden char marked in 1993-94, none were recaptured. In 1995, 132 char were marked and none were recaptured. The high proportion (18.6% or 548 fish) of char in the fish wheel catch in 1994 led us to believe that the sockeye salmon escapement may have historically been overestimated. The proportion of char in 1993 (0.5%) and 1995 (0.7%) may be more indicative of the degree of historical over apportionment to sockeye salmon than the high proportion observed in 1994.

We concluded from the hourly passage rate that daily migration timing is probably related to tide stage. However, we have not observed a diurnal bimodal entry pattern into Crescent River, so some other as yet unidentified variable(s) must also be influencing fish migration at this site. We have been unable to correlate fluctuations in water level or temperature to fish entry patterns into Crescent River.

### *Yentna River*

King and Tarbox (1990) indicated sockeye and pink salmon exhibited differential migratory behavior in the Yentna River. They found that sockeye salmon were proportionally higher in the fish wheel catch 1200-2400 h and pink salmon were more frequently captured 0600-1200 h. This observation identified a potential source of error in the use of total daily adjusted fish wheel catches to apportion sonar counts. To overcome this potential bias, fish wheels catches used to apportion

sonar counts were collected by operating the fish wheels in 4 time blocks of 6 h each over a 24 h period in 1993 and 1994. We determined that the degree of bias did not justify the additional expense of operating the fish wheels in this manner, and this method of fish wheel operation was discontinued in 1995.

Enumeration activities ceased on the Yentna River on 10 August. Migratory timing information could not be calculated for chum and coho salmon because migration continued past that date. The range for 1981-84=69.8%-92.0% (mean 78.7%) of the chum salmon escapement and 79.6%-89.9% (mean 84.8%) of the coho salmon escapement was recorded by 12 August (King and Tarbox 1986).

<sup>a</sup> Bendix Corp. multiple transducer sonar 1968-1977, side-scanning sonar 1978-1995.

<sup>b</sup> Based on creel census data from Sport Fish Division, Soldotna.

<sup>c</sup> Sport Fish Division Statewide Harvest Estimate, above the Soldotna Bridge (and sonar site) only.

<sup>d</sup> Combined Russian River and mainstem (above bridge) harvests.

<sup>e</sup> Sonar count less sport harvest reduced by 77,060 fish harvested by dip net at Hidden Creek.

FN: ESCSUM.XLS

Table 3. Late-run sockeye salmon escapement counts in eight index areas, Kenai River drainage, 1969-1995.

<sup>a</sup>Proportion accrued on last day (1981, 1982, 1984-1986, 1988) represents that portion of the escapement estimated to have entered the river after termination of counting operations.

<sup>b</sup>Inclusive dates: date proportion of escapement reached 10% through date proportion of escapement reached 90%.

FN: 95KECUM%.XLS

1984	231,685	11,141	220,544
1985	505,049	11,280	493,769
1986	275,963	11,952	264,011
1987	249,246	9,865	239,381
1988	204,000 <sup>d</sup>	9,387	195,000
1989	158,206	7,367	150,839
1990	144,136	6,831	137,305
1991	238,269	8,850	229,419
1992	184,178	6,550	177,628
1993	149,939	9,098	140,841
1994	205,117	13,596 <sup>e</sup>	191,521
1995	204,935	12,416	192,519

<sup>a</sup> Multiple transducer sonar counts rounded to the nearest thousand (1968-1978) from Namtvedt et al. (1979).

<sup>b</sup> From Cross et al. (1983): 1974-1980; FRED Div., Soldotna, Ak. files: 1981-1992; Fandrei, Cook Inlet Aquaculture Association: 1993-1995.

<sup>c</sup> Considered estimate of natural spawners above sonar site.

<sup>d</sup> Combined counts from weirs on Bear and Glacier Flat Creeks and surveys of spawning streams.

<sup>e</sup> Includes 290 fish not used for artificial propogation of Tustumena Lake, Fandrei (1995).

Table 12. Peak sockeye salmon escapement counts in seven index areas, Kaslof River drainage, 1975-1995.

Year	Nikolai Creek <sup>a</sup>	Crystal Creek <sup>a</sup>	Clear Creek <sup>a</sup>	Glacier Flat Creek <sup>b</sup>	Seepage Creek <sup>a</sup>	Moose Creek <sup>a</sup>	Bear Creek <sup>b</sup>	Total Index Count <sup>c</sup>
1975	5,700	400	300	14,400	3,700	3,300	27,700	55,500
1976	12,000	800	300	7,100	800	14,000	51,800	86,800
1977	29,100	600	1,800	5,800	800	16,600	58,000	112,700

1990	7,474	879	220	14,355	1,217	18,800	46,300	89,245
1991	21,582	391	1,223	12,068	1,661	18,105	68,880	123,910
1992	10,145	1,105	1,979	9,144	349	15,235	44,100	82,057
1993								
1994	63,723				13,347 <sup>e</sup>		36,002	36,002
1995							39,100	116,170
							29,017	29,017

<sup>a</sup> Commercial Fisheries Division stream survey counts (1975-85); FRED Division stream survey counts (1982-92); U.S. Biological Service weir count (Nikolai Creek 1994).

<sup>b</sup> FRED Division weir count, 1980-90, 1992. 1991 count is result of foot survey. 1993 count is result of foot and aerial survey and weir count, Cook Inlet Aquaculture Association, Gary Fandrei (personal communication).

<sup>c</sup> Counts standardized to common unit for years when entire stream not surveyed.

<sup>d</sup> Flagg (1986). Numbers rounded to nearest 100 fish.  
<sup>e</sup> U.S. Biological Service weir count (Glacier Flat Creek 1994). 1994 Glacier Flat Creek count includes 10,347 sockeye salmon passed through the weir and an estimated 3,000 sockeye salmon spawning downstream of the weir.

<sup>a</sup> No counts apportioned to chinook salmon in 1994 (8 chinook salmon were captured in the fish wheel). Counts were apportioned to Dolly Varden char.

<sup>b</sup> Count represents combined Chinook and Dolly Varden char (17 Chinook salmon were captured in the fish wheel).

Table 18. Estimated salmon escapement into the Crescent River, 28 June through 8 August 1995. Species composition based on fish wheel catches.

No. days for 80% <sup>c</sup>	31+	26+		21	23	22	25	21	23	23	24	23

<sup>a</sup> Proportion accrued on last day (1984-1986, 1988) represents that portion of the escapement estimated to have entered the river after termination of counting operations.

<sup>b</sup> Enumeration activities terminated on 16 July 1986. Estimated proportions from King and Tarbox (1988).

<sup>c</sup> Inclusive dates: date proportion of escapement reached 10% through date proportion of escapement reached 90%.
